PULSATILE CUTANEOUS NODULE IN ECCRINE POROMA

Kumpol Aiempanakit⁽¹⁾ - Thanadon Eksomtramage⁽¹⁾

Prince Of Songkla University, Internal Medicine, Division Of Dermatology, Hat Yai, Songkhla, Thailand⁽¹⁾

Background: Eccrine poroma, a benign sweat tumor, commonly presents with non-tender lesion locating on the distal extremities.

Observation: A 71-year-old woman had presented with a single pink papule on the left index for a year. A physical examination showed solitary well circumscribed, erythematous nodule with crust on the ulnar side of the left index finger. The dermoscopic finding showed chalice-form, cherry blossom vessels, structureless pink-white area, and hairpin vessels. Additionally, we found blinking light appearance described by the pulsatile vascular on the white surface in real time. The dermatopathologic findings were typical for eccrine poroma.

Key message: Eccrine poroma can be observed by real-time dermoscopy with the clinically blinking light appearance.
